a novel account of the evolution of language and the cognitive capacities on which language depends in from signal to symbol ronald planer and kim sterelny propose a novel theory of language that modern language is the product of a long series of increasingly rich protolanguages evolving over the last two million years arguing that language and cognition coevolved they give a central role to archaeological evidence and attempt to infer cognitive

capacities on the basis of that evidence which they link in turn to communicative capacities countering other accounts which move directly from archaeological traces to language planer and sterelny show that rudimentary forms of many of the elements on which language depends can be found in the great apes and were part of the equipment of the earliest species in our lineage after outlining the constraints a theory of the evolution of language should satisfy and filling in the details of their model they take up the evolution of words composite utterances and hierarchical structure they consider the transition from a predominantly gestural to a predominantly vocal form of language and discuss the economic and social factors that led to language finally they evaluate their theory in terms of the constraints previously laid out

intracellular checkpoint controls constitute a network of signal transduction pathways that protect cells from external stresses and internal errors external stresses can be generated by the continuous assault of dna damaging agents such as environmental mutagens ultraviolet uv light ionizing radiation or the reactive oxygen species that can arise during normal cellular metabolism in response to any of these assaults on the integrity of the genome the activation of the network of checkpoint control pathways can lead to diverse cellular responses such as cell cycle arrest dna repair or elimination of the cell by cell death apoptosis if the damage cannot be repaired moreover internal errors can occur during the highly orchestrated replication of the cellular genome and its distribution into daughter cells here the temporal order of these cell cycle events must be strictly enforced for example to ensure that dna replication is complete and occurs only once before cell division or to monitor mitotic spindle assembly and to prevent exit from mitosis until chromosome segregation has been completed thus well functioning checkpoint mechanisms are central to the maintenance of genomic integrity and the basic viability of cells and the fore are essential for proper development and survival the importance of proper functioning of checkpoints becomes plainly obvious under conditions in which this control network malfunctions and fails depending on the severity and timing failure of this machinery can lead to embryonic lethality genetic diseases and cancer
